Legend
F = page fault
B = process blocked
R = process ready
P*a*(X*b*) = processed page b of process a (X = R read, W write)
f= frame number

Clock - Fixed-Local Replacement, 30 frames (7 per process, 2 not allocated), quantum 3, input: Process1.txt ... Process4.txt
WB = dirty page(s) written back to the disk (1 time unit): a dirty victim page (paid by the faulting process) or, after the last execution of a process, all its dirty pages in paralle
Orange blocked-indicator cell = the write-back time unit (the process finishes at the end of the orange cell if it is the last write-back
* = dirty page (modified by a write after it was loaded)
Orange frame cell = frame locked while its dirty page is written back (also all dirty frames of a terminating process

Summary

PID	Turnaround time	Faults	Fault times	Write-backs
P1	31	5	0, 5, 10, 16, 22	1
P2	61	8	0, 6, 11, 17, 26, 36, 41, 46	2
P3	29	3	0, 7, 12	1
P4	69	9	0, 8, 13, 21, 27, 35, 40, 45, 60	2
